11:31 [notification icons] [status icons: HD, 4G, battery]

The screenshot shows a Zoom meeting interface. At the top, the time is 11:31 and there are notification icons. The status bar shows HD audio, 4G network, and battery level. The main content is a presentation slide with a blue background and a white text box. The slide title is 'b) Glandular tapetum:'. The text box contains a bulleted list of points. On the left side of the slide, there is a table of contents with four items: 'Introduction', 'Anther development', 'Glandular tapetum', and 'Secretory tapetum'. At the bottom of the slide, there is a 'Click to add notes' button.

**b) Glandular tapetum:**

- The cells of glandular tapetum remains intact throughout microspore development.
- They secrete their substances from their inner faces. Secretory tapetal cells are thin and possess almost all cell organelles like mitochondria, plastids, dictyosomes etc.
- Just before the pollen mother cells undergo meiosis, the walls of the tapetal cells become thick and there is considerable increase in the no. of ribosomes and pro-ubisch bodies with the completion of pollen development proubish bodies pass into the anther locule from the tapetal cells and they are now called ubisch bodies and they coated over the pollen grains
- Eg:- Higher monocots and many dicots.

**(2) Foliose lichen stage:**

Simple crustose lichens may be followed by larger, leafy forms, such as *Parmelia*, *Dermatocarpon*, *Umbilicaria*, which grow on the slight accumulation of soil and humus. Foliose lichens further loosen the rock particles. They overshadow the crustose lichens which eventually die and decay thus increasing the amount of humus in the soil.

Hasna Zeba (You)

Hemanta Saha

Pavilion 09

12:58

**2. Xerosere:**

When succession initiates on a dry, bare land.

**3. Lithosere:**

It starts on a bare rock surface.

**Psammosere:**

Initiating on sandy habitats. Here the pioneer community comprises sand-binding grasses with runners, e.g. Spinifex and Ipomoea biloba

**5. Halosere:**

It starts in saline soil or water. Here the pioneer plants usually have succulent leaves and stem e.g., Suaeda maritima, Acanthus ilicifolius, Chenopodium, Basella and some species of Asclapias.

**6. Senile:**

It is the succession of micro-organisms and lower plants on dead plant parts and bodies.

**Eosere or Geosere:**

It is the development of vegetation in an era

Depending upon the nature of the habitat on which the plant succession begins seven types of seres may be distinguished:

1. Hydrosere:

When succession starts in aquatic habitat

Fig. 4.1. Diagram showing primary succession from water (i.e. Hydrosere)

Hasna Zeba (You)

Pavilion 09

12:59

**(3) Reed-Swamp stage:**

This stage is initiated in extremely shallow waters (i.e., hardly one to four feet deep). The area is invaded by amphibious plants like Scirpus, Typha, Phragmites etc. These plants remain only partly submerged in water. Their rhizomes are profusely branched and they are rooted in the bottom of the lake. These plants prevent light to reach submerged and floating plants which consequently die, and their dead remains settle down on the lake bottom raising its level further.

Now a second group of plants, such as Sagittaria, Alisma and Acorus etc., invades the area. Eventually the habitat is made unfit for the growth of the plants of reed-swamp stage. The soil becomes dry enough to afford a foothold for terrestrial species.

Pavilion 09

The phytochrome pigment was discovered by [Sterling Hendricks](#) and [Harry Borthwick](#) at the [USDA-ARS Beltsville Agricultural Research Center](#) in [Maryland](#) during a period from the late 1940 to the early 1960. Using a [spectrograph](#) built from borrowed and war-surplus parts, they discovered that red light was very effective for promoting germination or triggering flowering responses. The red light responses were reversible by far-red light, indicating the presence of a photoreversible pigment. The phytochrome pigment was identified using a [spectrophotometer](#) in 1959 by biophysicist [Warren Butler](#) and biochemist [Harold Siegelman](#). Butler was also responsible for the name, phytochrome.

In 1983 the laboratories of Peter Quail and Clark Lagarias reported the chemical purification of the intact phytochrome molecule, and in 1985 the first phytochrome [gene sequence](#) was published by Howard Hershey and Peter Quail. By 1989, molecular genetics and work with [monoclonal antibodies](#) that more than one type of phytochrome existed; for example, the [pca](#) plant was shown to have at least two phytochrome types (then called [type I](#) (found predominantly in dark-grown seedlings) and [type II](#) (predominant in green plants)). It is now known by [genome sequencing](#) that [Arabidopsis](#) has five phytochrome genes (PHYA - E) but that rice has only three (PHYA - C). While this probably represents the condition in several di- and monocotyledonous plants.
